27 **Abstract**

28 Nine isolates obtained from a great scallop hatchery in Norway were characterized  
29 using a polyphasic approach. Strains were Gram-negative, aerobic and motile rods with  
30 oxidative metabolism. Phylogenetic analysis based on the sequences of 16S rRNA and  
31 *rpoB* genes showed that these strains formed two different groups associated with  
32 members of the genus *Neptuniibacter*. DNA-DNA hybridization (DDH) and Average  
33 Nucleotide Identity (ANI) demonstrated that the isolates constituted two novel species  
34 of this genus, which can be phenotypically differentiated from their closest relatives.  
35 The names *Neptuniibacter marinus* sp. nov. and *Neptuniibacter pectenicola* sp. nov are  
36 proposed, with ATR 1.1<sup>T</sup> (=CECT 8938<sup>T</sup>=DSM 100783<sup>T</sup>) and LFT 1.8<sup>T</sup> (=CECT  
37 8936<sup>T</sup>=DSM 100781<sup>T</sup>) as respective type strains.

42 **Keywords:** *Neptuniibacter pectenicola* sp. nov.; *Neptuniibacter marinus* sp. nov.;  
43 *Oceanospirillaceae*; *Pecten maximus*

51  
52       The Great scallop, *Pecten maximus*, is a potential aquaculture species in Norway and  
53 other European countries, due to its high price and well established markets [5]. The  
54 technology used in Norwegian hatcheries is almost the same as in 1960's and most of  
55 them depend on static or flow-through systems (FTS). The scallops suffer high  
56 mortality rates in early life stages, most of them with bacterial ethiology [18]. To  
57 improve survival of larvae different methods have been proposed including recirculating  
58 systems (RAS). In order to compare the microbiota associated with these two  
59 production systems, FTS and RAS, samples of broodstock, larvae, microalgae, water,  
60 biofilm, biofilters and water treated with UV light were collected in an experimental  
61 hatchery in Norway. A total of 221 isolates were obtained, among which 9 were  
62 selected for this study because they appeared to constitute two new species within the  
63 genus *Neptuniibacter*.

64       The genus *Neptuniibacter*, described by Arahal *et al.* [1], belongs to the Family  
65 *Oceanospirillaceae* and it is only constituted by two species at the time of writing:  
66 *Neptuniibacter caesariensis* and *Neptuniibacter halophilus* [7]. Besides being  
67 respectively isolated from seawater and salt pan, bacteria belonging to these species  
68 have also been detected forming part of intestinal microbiota of rainbow trout,  
69 (*Oncorhynchus mykiss*) [8], being therefore not only related to marine environments.  
70 *Neptuniibacter* has been also studied by its capacity of assimilation of taurine-nitrogen  
71 [12] and its implication in the degradation of carbazole [17].

72       In this study, nine isolates obtained from different compartments in the hatchery  
73 were phenotypical, chemotaxonomical and genetically characterized to determine their  
74 taxonomic position.

75       Samples were collected from Scalpro AS, an experimental hatchery in Bergen,  
76 Norway. Samples of water, biofilm, biofilter, UV treated water and larvae were spread

6  
77 on Marine Agar 2216 (MA; Difco). Different colonies were isolated from plates,  
78 purified as pure cultures and stored at -80 °C in Marine Broth (MB; Pronadisa)  
79 supplemented with 20% (v/v) glycerol.

80 Genomic DNA of pure cultures was obtained using the ‘Instagene’ matrix (Bio-Rad),  
81 following the manufacturer’s recommendations. Amplification of 16S rRNA gene of the  
82 different strains was carried out using primers 27F (5’-  
83 AGAGTTTGATCCTGGCTCAG-3’) and 1510R (5’-GGTTACCTTGTTACGACTT-  
84 3’) as previously described by Lane [13]. Amplification of *rpoB* gene, codifying for the  
85 β-subunit of RNA polymerase, was obtained with primers PasrpoB-L (5’-  
86 GCAGTGAAAGARTTCTTTGGTTC-3’) and rpoB-R (5’-  
87 GTTGCATGTTNGNACCCAT-3’) following the protocol described by Korczak *et al.*  
88 [11]. Sequences of the reference strains were retrieved from GenBank/EMBL. Sequence  
89 data analysis was performed with DNASTAR Lasergene SEQMAN program.  
90 Sequences obtained for both genes were subjected to a BLAST search against the latest  
91 release of GenBank and compared with available results in EzTaxon-extended database  
92 for 16S rRNA gene sequences [10]. Phylogenetic analysis of sequences of both genes  
93 were conducted with the program MEGA 6.0 [24], using Neighbour-joining (NJ) and  
94 Maximum Likelihood (ML) algorithms with a bootstrap of 1000 replications.

95 Sequences of 16S rRNA gene obtained for our isolates showed a range of similarity  
96 of 96.09-97.15% with *N. caesariensis* MED92<sup>T</sup> (=CECT 7075<sup>T</sup>) and between 95.87%  
97 and 96.27% with *N. halophilus* antisso-13<sup>T</sup> (=LMG 25378<sup>T</sup>). The phylogenetic trees  
98 obtained by NJ and ML showed that these isolates formed two very robust and  
99 independent groups within the genus *Neptuniibacter* and well differentiated from other  
100 genera of the Family *Oceanospirillaceae* (Fig. 1). Phylogenetic study based on *rpoB*  
101 gene only permitted the comparison of our isolates with a few deposited reference

102 sequences, but the results previously obtained with 16S rRNA gene analysis were  
103 confirmed, showing the new isolates distributed into two groups separated from other  
104 *Neptuniibacter* (Fig. 2). One group comprised 3 isolates (LFT 1.8<sup>T</sup> [=CECT 8936<sup>T</sup>  
105 =DSM 100781<sup>T</sup>] LRS 1.6 [=CECT 8937] and LRS 1.10) all of them from scallop  
106 larvae, and the second one grouped 6 isolates (ATR 1.1<sup>T</sup> [=CECT 8938<sup>T</sup> =DSM  
107 100783<sup>T</sup>], ATR 1.2, ATR 1.5, BFR 2.2, BFR 3.3 and UV 2.5 [=CECT 8939 =DSM  
108 100784]) obtained from tank and UV-treated water and biofilter in the hatchery.

109 The isolates were phenotypically characterized by routine biochemical tests  
110 following the methodologies described by Romalde *et al.* [21] and MacFaddin [15].  
111 *Neptuniibacter caesariensis* CECT 7075<sup>T</sup> and *N. halophilus* LMG 25378<sup>T</sup> were  
112 included in all the experiments for comparative purposes.

113 Morphology and motility were observed by light microscopy (ICC50HD; Leica).  
114 Catalase activity was determined based on bubble production in H<sub>2</sub>O<sub>2</sub>. The oxidase  
115 activity was determined by oxidation of 1% (w/v) N,N,N',N'-tetramethyl-*p*-  
116 phenylenediamine. Gelatinase, lipase, and hydrolysis of aesculin and starch activities  
117 were analyzed on MA plates supplemented with 0.4%, 1%, 0.1% and 0.4% (w/v) of  
118 substrates, respectively. Growth at various temperatures (4-44 °C) was determined on  
119 MA plates. The optimum pH range for growth was examined in MB using appropriate  
120 biological buffers for adjusting the pH to 3, 5, 7, 8, 9, 10 and 11. Tolerance to different  
121 salinity concentrations was tested on tubes of Basal Medium (BM) with 4 g l<sup>-1</sup>  
122 neopeptone and 1 g l<sup>-1</sup> yeast extract supplemented with 0%, 0.5%, 1%, 1.5%, 2%, 2.5%,  
123 3%, 4%, 5%, 6%, 8% and 10% of NaCl and on the other hand, with 0%, 0.5%, 1%, 2%,  
124 3%, 4%, 5%, 6%, 7%, 10%, 12% and 15% of Sea Salts (Sigma-Aldrich) incubated at  
125 room temperature. Growth was determined by measuring the turbidity at 580nm in a  
126 MicroScan TurbidityMeter (Siemens).

127 Use of different compounds as sole carbon source was tested on Basal Medium Agar  
128 (BMA) containing 50% (v/v) of Artificial Sea Water (ASW: 23.38 g l<sup>-1</sup> NaCl, 24.65 g l<sup>-1</sup>  
129 <sup>1</sup> MgSO<sub>4</sub>x7H<sub>2</sub>O, 1.5 g l<sup>-1</sup> KCl, 2.2 g l<sup>-1</sup> CaCl<sub>2</sub>x2H<sub>2</sub>O), 6.1 g l<sup>-1</sup> Tris-HCl, 1 g l<sup>-1</sup> NH<sub>4</sub>Cl,  
130 0.075 g l<sup>-1</sup> K<sub>2</sub>HPO<sub>4</sub>, 0.028 g l<sup>-1</sup> FeSO<sub>4</sub>x7H<sub>2</sub>O and 1.8% (w/v) American bacteriological  
131 Agar (Pronadisa) supplemented with different substrates according Baumann and  
132 Baumann [4]. A cell suspension was prepared on MB and 1μl was inoculated using a  
133 Multipoint Inoculator (Denley). Plates were incubated during 10 days at 25 °C obtaining  
134 lectures every 24 h.

135 Additional biochemical test were analyzed using miniaturized systems API ZYM  
136 (bioMerieux) according to the manufacturer's instructions but using a Sea Salts solution  
137 (3.5% w/v) and incubating at 25 °C during 24 h.

138 All isolates showed white and translucent colonies, bacilar morphology and great  
139 motility by light microscopy. All of them were Gram negative and oxidase positive.  
140 Catalase activity was present only in scallop larvae isolates. This characteristic together  
141 with the differences in the growth at 37°C and gelatinase activity allowed us to  
142 distinguish the two groups of Norwegian isolates. Unlike previously described species,  
143 our isolates could grow at 4°C but not in a medium containing 6% of NaCl (w/v). They  
144 also could be differentiated from other *Neptuniibacter* in the ability of use as sole  
145 carbon source cellobiose, L-rhamnose, glycerol or L-histidine whereas were not able to  
146 use glutamic acid or putrescine among other substances (Table1).

147 The Norwegian isolates presented a low enzymatic activity in the API ZYM system.  
148 Phosphatase alkaline activity was observed for all strains whereas they showed variable  
149 results in esterase, leucine arylamidase and valine arylamidase activities (Fig. S1). Only  
150 the isolate LFT 1.8<sup>T</sup> was positive for esterase lipase and isolate BFR 3.3 was positive  
151 for acid phosphatase. The rest of activities of the API ZYM gallery were negative for all

152 isolates, even for Naphthol-AS-BI-phosphohydrolase activity that is positive in other  
153 *Neptuniibacter* species.

154 Genomic DNA for DNA-DNA hybridization (DDH) and determination of the G+C  
155 content was extracted using Wizard® Genomic DNA Purification Kit (Promega). The  
156 G+C content was determined from triplicate samples of strains ATR 1.1<sup>T</sup> and LFT 1.8<sup>T</sup>  
157 following the method described by González and Saiz-Jimenez [9], using EvaGreen and  
158 30% formamide. *Lactococcus lactis* subsp. *lactis* CECT 4433<sup>T</sup>, *Escherichia coli* CECT  
159 433<sup>T</sup>, *Neptuniibacter caesariensis* CECT 7075<sup>T</sup> and *Pseudomonas aeruginosa* CECT  
160 4122<sup>T</sup> were used as controls. DDH between strains ATR 1.1<sup>T</sup>, LFT 1.8<sup>T</sup> and *N.*  
161 *caesariensis* CECT 7075<sup>T</sup> were performed by the hydroxyapatite/microtitre method [28]  
162 with a hybridization temperature (T<sub>m</sub>) of 60 °C.

163 In addition, DNA of isolates ATR 1.1<sup>T</sup> and LFT 1.8<sup>T</sup> was extracted with High Pure  
164 PCR Template Preparation kit (Roche) and sequenced at Sistemas Genómicos  
165 (Valencia, Spain) using Illumina paired-end sequencing technology. The quality of  
166 reads was analyzed using Trimmomatic 0.32 [6]. Genome assembly was performed  
167 using SPAdes 3.6.1 [19]. Accession numbers of whole genome sequences of LFT 1.8<sup>T</sup>  
168 and ATR 1.1<sup>T</sup> are LUTR00000000.1 and LUTS00000000.1, respectively. The versions  
169 described in this paper are version LUTR01000000.1 and LUTS01000000.1,  
170 respectively. The Average Nucleotide Identity (ANI), using BLAST (ANIb) and  
171 MUMmer (ANIm) algorithms, was calculated using the software J-species (V1.2.1) as  
172 described by Richter and Roselló-Móra [20]. OrthoANI percentages were calculated as  
173 described Lee et al. [10]. *In silico* DDH value was estimated between strains ATR 1.1<sup>T</sup>,  
174 LFT 1.8<sup>T</sup> and *N. caesariensis* MED92<sup>T</sup> (Accession number AAOW00000000.1) using  
175 the genome-to-genome distance calculator (GGDC2.0) [2, 3, 16].

176 DDH reassociation values obtained for strains ATR 1.1<sup>T</sup> and LFT 1.8<sup>T</sup> are shown in  
177 Table 2. For ATR 1.1<sup>T</sup> DDH values of 56.46%, 43.73 and 51.07% were obtained with  
178 strains LFT 1.8<sup>T</sup>, and respectively. For strain LFT 1.8<sup>T</sup>, DDH values of 32.1% with *N.*  
179 *caesariensis* CECT 7075<sup>T</sup> and 42.0% with *N. halophilus* LMG 25378<sup>T</sup> were observed.  
180 Results obtained using *in silico* DDH for ATR 1.1<sup>T</sup> were 24.50% ± 2.39 with LFT 1.8<sup>T</sup>  
181 and 18.00% ± 2.25 with *N. caesariensis* MED 92<sup>T</sup> (Table 2). The strain LFT 1.8<sup>T</sup>  
182 showed a percentage of similarity of 18.10% ± 2.25 with *N. caesariensis* MED92<sup>T</sup>. In  
183 any case, the values were lower than the 70% established as threshold for species  
184 definition [28].

185 ANIb, ANIm and OrthoANI values between ATR 1.1<sup>T</sup>, LFT 1.8<sup>T</sup> and *N. caesariensis*  
186 MED92<sup>T</sup> are listed in Table 2. Values ranged from 71.25% to 81.59% for ANIb, from  
187 83.28% to 86.06% for ANIm, and from 72.12 to 81.67 for Ortho ANI. Values obtained  
188 from the three indexes were consistent and below the proposed cut-off for species  
189 boundary (95~96%) [20].

190 The DNA G+C mol% content of strains ATR 1.1<sup>T</sup> and LFT 1.8<sup>T</sup> was determined by  
191 whole genome sequencing data and also was estimated by thermal denaturation method.  
192 G+C contents of ATR 1.1<sup>T</sup> and LFT 1.8<sup>T</sup> were of 42.8 mol% and 45.7 mol% when  
193 calculated from the whole genome sequences, and of 47.5 mol% and 49.3 mol% by the  
194 fluorimetric method. Thus, variations of 4.7% and 3.6% were observed for the G+C  
195 content of these strains depending on the procedure utilized. In the original description  
196 of *N. halophilus*, Chen *et al.* [7] reported that the type strain presents a G+C content of  
197 54.2 ± 1.0 mol%. This value could mean a conflict when compared to that of strain  
198 ATR 1.1<sup>T</sup> (obtained from genome sequence) due to the fact that these type strains differ  
199 in more than 10 mol%, and therefore they would belong theoretically to different genera  
200 [23, 27, 28]. Such incongruence does not exist when compared with the value obtained

201 by the fluorimetric method. However, it is important to note that the result by Chen et  
202 al. [7] was obtained by using HPLC method, that although seems to be more accurate  
203 the the fluorimetric technique, is still an indirect method for of G+C content  
204 measurement.

205 Whole-cell fatty acid analysis was concurrently performed on cells of the isolates  
206 ATR 1.1<sup>T</sup>, LFT 1.8<sup>T</sup>, *N. caesariensis* CECT 7075<sup>T</sup> and *N. halophilus* LMG 25378<sup>T</sup>  
207 grown for 2 days at 25° C on MA (Difco). Extraction and analysis of whole-cell fatty  
208 acids was carried out using the MIDI system in accordance with the protocols and  
209 instrument specifications recommended by the manufacturer [22] using Phospholipid  
210 Fatty Acids (PFLAD1) and Environmental Aerobes (TSBA) databases. Extraction and  
211 analysis of respiratory quinones and polar lipids were carried out by the Identification  
212 Service of the DSMZ using thin layer chromatography following the methodology  
213 described by Tindall [25, 26].

214 Evaluation of fatty acid composition revealed that the two groups of Norwegian  
215 isolates, *N. caesariensis* and *N. halophilus* shared the major fatty acids, including C<sub>10:0</sub>  
216 3OH, C<sub>16:0</sub>, Summed Feature 3 (C<sub>16:1</sub>ω7c /C<sub>16:1</sub> ω6c) and Summed Feature 8 (C<sub>18:1</sub>ω7c  
217 or C<sub>18:1</sub> ω6c) although differences in their percentages were observed (Table 3). Strain  
218 ATR 1.1<sup>T</sup> could be differentiated from the other species by a high percentage of C<sub>18:0</sub>  
219 (Table 3).

220 Regarding to polar lipids and respiratory quinones analysis, ATR 1.1<sup>T</sup> presented  
221 diphosphatidylglycerol, phosphatidylethanolamine, phosphatidylglycerol and an  
222 unidentified phosphoaminolipid as the major compounds of polar lipids profile. A  
223 weak presence of unknown phospholipid, glycolipid and aminolipid was also detected  
224 (Fig. 3A). Isolate LFT 1.8<sup>T</sup> showed a polar lipid profile formed by  
225 phosphatidylethanolamine and an unknown phosphoaminolipid as major compounds. A

226 moderate amount of phosphatidylglycerol and diphosphatidylglycerol and weak peaks  
227 of unidentified phosphoaminolipid, phospholipid and lipid were detected (Fig.3B).  
228 Ubiquinone Q8 was the principal respiratory quinone in both groups of isolates.

229 According to the results obtained in the phenotypic characterization, genomic and  
230 phylogenetic analysis, and chemotaxonomic studies, we conclude that these groups of  
231 isolates constitute two novel species within the genus *Neptuniibacter* for which the  
232 names *Neptuniibacter marinus* sp. nov. and *Neptuniibacter pectenicola* sp. nov are  
233 proposed, with strains ATR 1.1<sup>T</sup> (=CECT 8938<sup>T</sup>= DSM 100783<sup>T</sup>) and LFT 1.8<sup>T</sup>  
234 (=CECT 8936<sup>T</sup>= DSM 100781<sup>T</sup>) as the type strains.

235

#### 236 **Description of *Neptuniibacter marinus* sp. nov.**

237 *Neptuniibacter marinus* (ma. ri' nus. L. masc. adj. *marinus*, from the seawater.)

238 Cells are rods, motile, Gram-negative, oxidase positive and catalase negative.  
239 Colonies are white-transparent, with entire margins and 1-2 mm of diameter on MA. The  
240 temperature range for growth is 4°C – 30°C (optimum: 25°C), whereas the pH range is  
241 pH 7.0-10.0, except for the strains ATR 1.1<sup>T</sup> and BFR 2.2, which can grow at pH 5.  
242 Growth in medium without NaCl or sea salts was not observed. The range of NaCl to  
243 grow is 1-8% (optimum: 2.5-3%), except for isolate UV 2.5 which only can grow at 2.5-  
244 3% NaCl, and for Sea Salts the range is 2-6% (optimum of 5%). All strains are negative  
245 for indol, citrate and reduction of nitrates to nitrites except the type strain, ATR 1.1<sup>T</sup>. No  
246 hydrolysis of gelatin, starch, tween 80 and aesculine is observed. According to API  
247 ZYM, all strains present alkaline phosphatase and leucine arylamidase activity except  
248 isolate BFR 3.3. Isolates ATR 1.1<sup>T</sup>, ATR 1.2 and ATR 1.5 show esterase (C4) activity.  
249 Valine arylamidase is present in ATR 1.1<sup>T</sup>, ATR 1.2, BFR 2.2 and BFR 3.3, and only  
250 strain BFR 3.3 show acid phosphatase activity. All strains can use as sole carbon source

251  $\beta$ -hydroxybutyric acid, fumaric acid, citric acid, lactic acid, propionic acid, *trans*-  
252 aconitic acid, malic acid, succinic acid, L-rhamnose, D-alanine, piruvate, sodium  
253 acetate, cellobiose and glycerol. Type strain ATR 1.1<sup>T</sup> can use L-serine. Major fatty  
254 acids detected are Summed feature 3 which contains C<sub>16:1</sub>  $\omega$ 7c/ C<sub>16:1</sub>  $\omega$ 6c (36.8%), C<sub>16:0</sub>  
255 (25.7%), Summed feature 8 composed by C<sub>18:1</sub>  $\omega$ 7c or C<sub>18:1</sub>  $\omega$ 6c (23.7%), C<sub>10:0</sub> 3OH  
256 (5.1%) and C<sub>18:0</sub> (4.1%).

257 Polar lipids profile contains diphosphatidylglycerol, phosphatidylethanolamine,  
258 phosphatidylglycerol and an unidentified phosphoaminolipid as major compounds and  
259 to a lesser extent unknown phospholipid, aminolipid and glycolipid. Ubiquinone Q8 is  
260 major respiratory quinone.

261 The type strain ATR 1.1<sup>T</sup> (= CECT 8938<sup>T</sup>=DSM 100783<sup>T</sup>) was isolate from water of a  
262 tank in a hatchery of Great scallop (*Pecten maximus*) in Bergen, Norway (60° 30'  
263 53.77" N 4° 54' 14.75" W). The DNA G+C content of type strain is 42.8 mol%.

264

265 **Description of *Neptuniibacter pectenicola* sp. nov.**

266 *Neptuniibacter pectenicola* (pec. te. ni' co. la., L. n. *pecten* scallop; L. suff *-cola*  
267 dweller; N. L. n. *pectenicola* scallop dweller).

268 Cells are rods, motile, Gram-negative, oxidase and catalase positive. Colonies are  
269 white-transparent, with entire margins and 1-2 mm of diameter on MA. All strains can  
270 grow from 4°C to 37°C with an optimum of 25°C. All isolates require at least 1% of  
271 NaCl or 2% of Sea Salts in the medium to grow. pH tolerance range from 7 to 10 except  
272 for type strain who can grow at pH 5. Negative to indol, citrate, reduction of nitrates and  
273 hydrolysis of starch, tween 80 and aesculine but isolates can hydrolyze gelatin.  
274 According to API ZYM, all strains present alkaline phosphatase and valine arylamidase  
275 but not lipase (C14), cystine arylamidase, trypsin,  $\alpha$ -chymotrypsin, acid phosphatase,

276 naphthol-AS-BI-phosphohydrolase,  $\alpha$  and  $\beta$ - galactosidase,  $\beta$ -glucuronidase,  $\alpha$  and  $\beta$ -  
277 glucosidase, N-acetyl- $\beta$ -glucosaminidase,  $\alpha$ -mannosidase and  $\alpha$ -fucosidase. Strains LFT  
278 1.8<sup>T</sup> and LRS 1.6 also present esterase (C4) and leucine arylamidase activities. Type  
279 strain also produces esterase lipase (C8).

280 All isolates can use as sole carbon source the following compounds:  $\gamma$ - aminobutyric  
281 acid,  $\beta$ -hydroxybutyric acid, fumaric acid, citric acid, lactic acid, propionic acid, *trans*-  
282 aconitic acid, malic acid, succinic acid, cellobiose, L- histidine, D-alanine, L-rhamnose,  
283 pyruvate and sodium acetate but they can not use *myo*-inositol, N-acetyl-glucosamine,  
284 D-sorbitol, glycine, aspartic acid, arabinose, L-leucine, L-threonine, glutamic acid, L-  
285 arginine, sucrose, trehalose, sarcosine, putrescine, lysine, D-manitol, salicine, glycerol,  
286 D-saccharic acid, gluconic acid, amigdaline, melibiose, lactose, maltose, D-mannose, D-  
287 galactose, tyrosine, L-citrulline, ornithine, D-ribose, D-xylose, glucose and D-fructose.  
288 Only strain LRS 1.10 can use L- serine as unique carbon source. Major fatty acids  
289 present on type strain are Summed feature 8 containing C<sub>18:1</sub>  $\omega$ 7c or C<sub>18:1</sub>  $\omega$ 6c (37.00%),  
290 Summed feature 3 composed by C<sub>16:1</sub>  $\omega$ 7c/ C<sub>16:1</sub>  $\omega$ 6c (23.0%), C<sub>16:0</sub> (22.8%), C<sub>10:0</sub> 3OH  
291 (8.7%) and C<sub>12:1</sub> 3OH (2.0%).

292 Polar lipids profile is formed by phosphatidylethanolamine and unknown  
293 phosphoaminolipid as major components, phosphatidylglycerol and  
294 diphosphatidylglycerol in a moderate quantity and weak amount of unidentified lipid  
295 and phospholipid. The major respiratory quinone is ubiquinone Q-8.

296 The type strain LFT 1.8<sup>T</sup> (=CECT 8936<sup>T</sup>=DSM 100781<sup>T</sup>) was isolate from Great scallop  
297 (*Pecten maximus*) larvae in a hatchery of Bergen, Norway (60° 30' 53.77" N 4° 54'  
298 14.75" W). The DNA G+C content of type strain is 45.7 mol%.

301 **Emended description of the genus *Neptuniibacter* Arahal *et al.* 2007 emended by**  
302 **Chen *et al.* 2012.**

303 The description of the genus *Neptuniibacter* is based on that given previously by Arahal  
304 *et al.* [1] with the following modifications. All species of the genus are catalase positive  
305 except *Neptuniibacter marinus* and the minimum G+C content of the genus is 42.8  
306 mol%.

439 \*ND, not determined

440 Genomes used in the *in silico* analyses: *N. marinus* sp. nov. ATR 1.1<sup>T</sup> (LUTR00000000.1); *N.*  
 441 *pectenicola* LFT 1.8<sup>T</sup> (LUTS00000000.1); *N. caesariensis* MED92<sup>T</sup> (AAOW00000000.1).

442

443

444

445

446 **Table 3:** Fatty acid composition obtained from type strains of *N. marinus* sp. nov., *N.*  
 447 *pectenicola* sp. nov., *N. caesariensis* and *N. halophilus*.

Major fatty Acids	<i>N. marinus</i> sp. nov. ATR 1.1 <sup>T</sup>	<i>N. pectenicola</i> sp. nov. LFT 1.8 <sup>T</sup>	<i>N. caesariensis</i> CECT 7075 <sup>T</sup>	<i>N. halophilus</i> LMG 25378 <sup>T</sup>
C <sub>10:0</sub> 3OH	5.1	8.7	5.0	5.2
C <sub>12:1</sub> 3OH	1.4	2.0	ND	ND
C <sub>14:0</sub>	1.3	<i>tr</i>	<i>tr</i>	<i>tr</i>
Summed feature 3	36.8	23.0	39.0	42.2
C <sub>16:0</sub>	25.7	22.8	15.3	15.1
C <sub>18:1</sub> ω9 <sub>c</sub>	1.0	ND	ND	<i>tr</i>
Summed feature 8	23.7	37.0	37.3	33.5
C <sub>18:0</sub>	4.1	1.9	1.2	<i>tr</i>
C <sub>19:0</sub> 10- methyl	ND	1.9	ND	<i>tr</i>

448 Values are percentages of the total fatty acids; fatty acids that make up <1 % of the total are indicated by  
 449 *tr*. ND: Not detected. For unsaturated fatty acids, the position of the double bond is located by counting  
 450 from the methyl (ω) end of the carbon chain. *cis* isomer is indicated by the suffixes *c*. Summed features  
 451 are groups of two fatty acids that cannot be separated by GLC with the MIDI system. Summed feature 3  
 452 contains C<sub>16:1</sub>ω7<sub>c</sub>/C<sub>16:1</sub>ω6<sub>c</sub> and Summed feature 8 contains C<sub>18:1</sub>ω7<sub>c</sub> and/or C<sub>18:1</sub>ω6<sub>c</sub>. All data obtained in  
 453 the present study.

### Figure legends

462 **Fig. 1.** Phylogenetic reconstruction based on the nucleotide sequences of 16S rRNA  
463 gene by the ML algorithm, showing the position of the novel *Neptuniibacter* species.  
464 Bootstrap values (expressed as percentages of 1000 replications) greater than 50% are  
465 shown at the nodes. Bold circles indicate that corresponding nodes were coincident in  
466 the tree generated with NJ algorithm. Bar, 0.02 substitutions per nucleotide position.

467

468 **Fig. 2.** Phylogenetic reconstruction based on the nucleotide sequences of *rpoB* gene by  
469 the NJ algorithm, showing the position of the novel *Neptuniibacter* species. Bootstrap  
470 values (expressed as percentages of 1000 replications) are shown at the nodes. Bar, 0.05  
471 substitutions per nucleotide position.

472

473 **Fig. 3.** Polar lipid profiles of type strains of *N. marinus* sp. nov. ATR 1.1<sup>T</sup> (A) and *N.*  
474 *pectenicola* sp. nov. LFT 1.8<sup>T</sup> (B). DPG: Diphosphatidylglycerol; PE:  
475 Phosphatidylethanolamine; PG: Phosphatidylglycerol; PL: Phospholipid; PN:  
476 Phosphoaminolipid; GL: Glycolipid; AL: Aminolipid; L: lipid.
